

## MIDTERM EXAM

This exam is due at 9AM Saturday, 3/17. As usual, you are not to discuss the exam with other students until after the exam is due. The exam must be entirely your own work. Answer all questions.

- (1) Below are data on  $x$  and  $y$ , drawn from a process where

$$y | x \sim N(f(x), 1)$$

and  $f$  is an unknown function. Suppose that our prior makes

$$f(x_1) - f(x_2) \sim N(0, |x_1 - x_2|)$$

and makes the covariance of  $f(x_1) - f(x_2)$  with  $f(x_3) - f(x_4)$  zero if  $(x_1, x_2)$  and  $(x_3, x_4)$  do not overlap. In other words,  $f(x)$  behaves like a Wiener process. Treat the prior on  $f(0)$  as  $N(0, 10)$ .

The Data		
	x	y
1	1.00	3.00
2	2.00	7.00
3	5.00	8.00
4	6.00	5.00
5	8.00	1.00
6	11.00	2.00

- (a) Calculate the posterior expected value, given the observed  $x$  and  $y$  data, of  $f(x)$  at 20 equally spaced  $x$  values points between 0 and 12.
- (b) Add to the plot  $\pm$  one standard deviation bands for the distribution of  $f$  values at these 20  $x$  points.
- (c) Add to the plot  $\pm$  one standard deviation bands for a newly drawn  $y$  value at each of the 20  $x$  points. This will characterize the distribution of forecast errors from our estimated  $f$  function, and of course will be wider than the bands for  $f$ .
- (d) Plot the data as individual points, again on the same plot.
- (2) Suppose we have 100 observations on  $y$  drawn i.i.d. from the exponential distribution, i.e. with pdf

$$e^{-y}.$$

Suppose also that the sampling has been subject to selection with the probability of selection  $w$  distributed on  $(0,1)$  with some pdf  $g(w)$ .

- (a) Show that the sample average of the ratios  $y_i/w_i$  has expectation 1.0 and converges to this value as the sample size goes to infinity.
- (b) Show that if  $w$  is independent of  $y$ , the sample average of  $y_i$  itself, without any use of  $w_i$  in the averaging, has expectation 1.0 and converges to this value as sample size goes to infinity.

Date: March 16, 2018.

- (c) Compare the variance of the sample average of  $y_i$  to that of the sample average of  $y_i/w_i$ , maintaining the assumption of independence of  $w$  and  $y$ . Consider two cases:  $g(w) \equiv 1$  and  $g(w) = 2w$ .
- (d) Now suppose that  $w$  takes on only two values, .25 and .5, with each value having probability .5. Calculate the variance of the sample mean of the 100 draws of  $y_i/w_i$  for the case where  $w_i$  is independent of  $y_i$ , and also when instead  $w_i = .5$  for all  $y_i > \log(2)$  and  $w_i = .25$  for all  $y_i < \log(2)$ . (Note that for exponentially distributed  $y$ ,  $P[y < \log(2)] = .5$ .)
