

RANDOM EFFECTS AS A WEIGHTED AVERAGE

The model:

$$y_{ig} = X_{ig}\beta + v_g + \varepsilon_{ig}, i = 1, \dots, n, g = 1, \dots, M \quad (1)$$

$$v_g | X \sim N(0, \tau^2), \quad \varepsilon_{ig} \sim N(0, \sigma^2). \quad (2)$$

In addition we assume that conditional on X (the full $nm \times k$ matrix of X_{ig} values) the ε and v vectors are jointly normal with diagonal covariance matrix.

As is explained in earlier notes, in this model the GLS estimate of β with known σ^2 and τ^2 takes the form of a weighted average of the between and within regression estimates, where the within estimate is the fixed effects estimator (or equivalently the estimate based on the deviations from group means of y and X) and the between estimate is the estimate based on group-mean data (i.e. the M data points generated by taking means across i for each g). The formula derived in the earlier notes was

$$\hat{\beta}_{GLS} = (X^{*'}X^*)^{-1}X^{*'}y^* = (\sigma^{-2}\tilde{X}'\tilde{X} + \delta^2\bar{X}'\bar{X})^{-1}(\sigma^{-2}\tilde{X}'\tilde{X}\hat{\beta}_w + \delta^2\bar{X}'\bar{X}\hat{\beta}_b). \quad (3)$$

The earlier notes did not give an explicit formula for δ as a function of σ^2 and τ^2 or for the likelihood function as a function of the between and within residual sums of squares. These notes fill in these gaps.

Since the residual covariance matrix has the form

$$\Omega = I_M \otimes \tilde{\Omega} = I_M \otimes (\sigma^2 I_n + \tau^2 \mathbf{1}), \quad (4)$$

the GLS estimator can be described as OLS on transformed data, where y and X are pre-multiplied by W

$$W = I_m \otimes \tilde{W} = I_m \otimes \left(\sigma^{-1} \left(I - \frac{1}{n} \mathbf{1} \right) + \frac{\delta}{n} \mathbf{1} \right) \quad (5)$$

$$\tilde{W}^2 = \tilde{\Omega}^{-1} = \sigma^{-2} \left(I - \frac{1}{n} \mathbf{1} \right) + \frac{\delta^2}{n} \mathbf{1} \quad (6)$$

$$\therefore \tilde{W}^2 \tilde{\Omega} = \left(\sigma^{-2} \left(I - \frac{1}{n} \mathbf{1} \right) + \frac{\delta^2}{n} \mathbf{1} \right) (\sigma^2 I + \tau^2 \mathbf{1}) = I \quad (7)$$

$$\therefore -\frac{1}{n} + \frac{\delta^2 \sigma^2}{n} + \tau^2 \delta^2 = 0. \quad (8)$$

From this we can conclude that $\delta^2 = 1/(\sigma^2 + n\tau^2)$.

The $\tilde{\Omega}$ matrix has $n - 1$ eigenvalues of σ^2 (corresponding to eigenvectors that sum to one) and 1 eigenvalue of $\tau^2 n + \sigma^2$. The full Ω matrix therefore has $M(n - 1)$ eigenvalues of σ^2 and M of $\tau^2 n + \sigma^2$. The log likelihood function can be written as

$$\frac{Mn}{2} \log(2\pi) - \frac{M}{2} \log(\tau^2 n + \sigma^2) - \frac{Mn}{2} \log(\sigma^2) - \frac{\tilde{u}'\tilde{u}}{2\sigma^2} - \frac{\bar{u}'\bar{u}}{2(\tau^2 + \sigma^2/n)}, \quad (9)$$

where \tilde{u} are the residuals from the between regression and \bar{u} are the residuals from the within regression.

The conditional posterior distribution on β given σ^2 and τ^2 is $N(\hat{\beta}_{GLS}, (X'\Omega^{-1}X)^{-1})$, where

$$\hat{\beta}_{GLS} = (\sigma^{-2}\tilde{X}'\tilde{X} + (\sigma^2 + \tau^2n)^{-1}\bar{X}'\bar{X})^{-1}(\sigma^{-2}\tilde{X}'\tilde{X}\hat{\beta}_w + \delta^2\bar{X}'\bar{X}\hat{\beta}_b) \quad (10)$$

$$X'\Omega^{-1}X = \sigma^{-2}\tilde{X}'\tilde{X} + (\sigma^2 + \tau^2n)^{-1}\bar{X}'\bar{X} \quad (11)$$

Conditional on β ,

$$\sigma^{-2} \sim \text{Gamma}(Mn - 1, \tilde{u}'\tilde{u}) \quad (12)$$

$$(\tau^2 + \sigma^2)^{-1} \sim \text{Gamma}(M - 1, \bar{u}'\bar{u}), \quad (13)$$

with these two random variables independent. Of course this means that σ^2 and τ^2 themselves are dependent.

These results suggest a particularly simple way to sample from the posterior on σ^2 , τ^2 and β . Assuming we have some initial estimates — for example by applying OLS to estimate β and estimating $\tau^2 + \sigma^2/n$ as $\bar{u}'\bar{u}/M$, σ^2 as $\tilde{u}'\tilde{u}/(Mn)$:

- (1) Draw β from its normal conditional posterior above, and use the draw to construct \tilde{u} and \bar{u} .
- (2) Draw σ^{-2} and $\tau^2 + \sigma^2/n$ from their conditional posteriors above.
- (3) Return to 1.

With this scheme, $\bar{X}'\bar{X}$, $\tilde{X}'\tilde{X}$, β_w , and β_b can be computed once, before the iterations start. The MCMC sampled values are constructed by reweighting these objects.
